Introduction

The bayesQRsurvey package implements four approaches for Bayesian weighted quantile regression:

- Asymmetric Laplace Distribution (ALD): Uses the ALD as a working likelihood, incorporating survey weights in the scale parameter. Posterior inference is carried out via Gibbs sampling.
- Score: Builds a working likelihood from estimating equations (score function), following Huang, Xu and Tashnev (2015). It accounts for survey weights and uses adaptive Metropolis–Hastings for inference.
- Approximate: Proposed by Wang, Kim and Yang (2018), this method approximates the posterior using the sampling distribution of summary statistics. The Score-based method is a special case, also using adaptive Metropolis–Hastings.
- Expectation—Maximization (EM) Algorithm: Implemented for multivariate quantile regression. It leverages the ALD mixture representation to update latent variables and parameters iteratively, targeting posterior modes with much lower computational cost than MCMC.

Also, this vignette compares the performance of **bayesQR** with the three MCMC methods implemented in **bayesQRsurvey** using a simulated dataset and the classic Prostate cancer dataset included in the **bayesQR** package.

We estimate the 25th, 50th, and 75th quantile and compare coefficient estimates across all methods.

bayesQRsurvey usage examples

Let's begin showing how to use bayesQRsurvey methods:

```
library(bayesQRsurvey)
```

Creating Priors

The prior() function provides a unified interface to define prior distributions for both univariate (bqr.svy) and multivariate (mo.bqr.svy) Bayesian quantile regression models.

It returns an S3 object that store the prior information in a structured way.

The prior() function creates an S3 object of class bqr_prior that contains the prior information. If the object is omitted in a call to bqr.svy() or mo.bqr.svy(), a standard vague prior is used by default.

Doing an example using bayesQRsurvey

```
my_prior <- bayesQRsurvey::prior(</pre>
 beta_x_mean = rep(0, 4),
 beta_x_cov = diag(1000, 4),
 sigma_shape = 0.001,
 sigma rate = 0.001
print(my_prior)
#> Prior beta_x_mean: 0 0 0 0
#> beta_x_cov:
#>
    [,1] [,2] [,3] [,4]
#> [1,] 1000 0 0
#> [2,] 0 1000
                   0
#> [3,] 0 0 1000
#> [4,] 0
            0 0 1000
#> sigma IG: shape=0.001, rate=0.001
#> beta_y_mean: diffuse (all zeros)
#> beta_y_cov: diffuse (large diagonal: 1e6)
```

Fitting models with different methods

We use the **mtcars** dataset to fit three models — **ALD**, **Score**, and **Approximate** — each at the 0.5 quantile.

```
set.seed(123)

data(mtcars)

mtcars_scaled <- mtcars
mtcars_scaled[, c("wt", "hp", "cyl")] <- scale(mtcars[, c("wt", "hp", "cyl")])

form <- mpg ~ wt + hp + cyl</pre>
```

```
fit_ald <- bqr.svy(</pre>
  form,
  data
          = mtcars_scaled,
  quantile = 0.5,
 method = "ald",
          = 20000,
 niter
         = 10000,
 burnin
 thin
          = 5,
 prior = my_prior,
 verbose = TRUE
)
#> Iteration 2000 of 20000
#> Iteration 4000 of 20000
#> Iteration 6000 of 20000
#> Iteration 8000 of 20000
#> Iteration 10000 of 20000
#> Iteration 12000 of 20000
#> Iteration 14000 of 20000
#> Iteration 16000 of 20000
#> Iteration 18000 of 20000
fit_score <- bqr.svy(</pre>
 form,
          = mtcars_scaled,
 data
 quantile = 0.5,
 method = "score",
 niter = 20000,
 burnin = 10000,
 prior = my_prior,
 thin
          = 5,
 verbose = TRUE
#> Iteration 2000 of 20000
#> Iteration 4000 of 20000
#> Iteration 6000 of 20000
#> Iteration 8000 of 20000
#> Iteration 10000 of 20000
#> Iteration 12000 of 20000
#> Iteration 14000 of 20000
#> Iteration 16000 of 20000
#> Iteration 18000 of 20000
#> Iteration 20000 of 20000
fit_approx <- bqr.svy(</pre>
 form,
 data
          = mtcars_scaled,
  quantile = 0.5,
 method = "approximate",
 niter = 20000,
  burnin = 10000,
          = my_prior,
  prior
 thin
           = 5,
  verbose = TRUE
```

```
#> Iteration 0 of 20000

#> Iteration 2000 of 20000

#> Iteration 4000 of 20000

#> Iteration 6000 of 20000

#> Iteration 8000 of 20000

#> Iteration 10000 of 20000

#> Iteration 12000 of 20000

#> Iteration 14000 of 20000

#> Iteration 16000 of 20000

#> Iteration 18000 of 20000
```

For the EM algorithm, the model is fitted by projecting the multivariate response onto a set of directions. These directions can be supplied by the user through an object U; if not provided, the algorithm will automatically generate them.

```
data(mtcars)
Y <- cbind(mtcars$mpg, mtcars$hp)
set.seed(123)
d \leftarrow ncol(Y)
n_dir <- 3
U <- matrix(NA_real_, d, n_dir)</pre>
for (k in 1:n_dir) {
  u_k <- rnorm(d)</pre>
  U[, k] <- u_k / sqrt(sum(u_k^2))</pre>
fit_mo <- mo.bqr.svy(</pre>
  cbind(mpg, hp) ~ wt + cyl + disp,
           = mtcars,
  quantile = c(0.25, 0.5, 0.75),
           = U,
  prior
           = my_prior,
  n_dir = n_dir,
  max_iter = 5000,
  verbose = FALSE
gamma_U <- vector("list", n_dir)</pre>
for (k in 1:n_dir) {
  gamma_U[[k]] <- pracma::nullspace(t(U[, k]))</pre>
}
fit_mo <- mo.bqr.svy(</pre>
  cbind(mpg, hp) ~ wt + cyl + disp,
  data
         = mtcars,
  quantile = c(0.25, 0.5, 0.75),
           = U,
  gamma_U = gamma_U,
  prior = my_prior,
```

```
n_dir = n_dir,
max_iter = 5000,
verbose = FALSE
)
```

We can also fit several quantiles at once by passing a vector of probabilities with c(), for example quantile = c(0.25, 0.5, 0.75).

Model Output: Print and Summary Methods

There are also print() and summary() created for the output objects of bayesQRsurvey We can explore the return of the object bqr.svy

Table 1: Model Information - ALD Method

Information	Value
Method	ald
Quantiles	0.5
Draws	10000
Burn-in	10000
Thin	5

```
# Summary method - detailed convergence diagnostics will be shown in summary section

# Access posterior draws - show structure
if (!is.null(fit_ald$draws)) {
   knitr::kable(
    head(as.data.frame(fit_ald$draws), 6),
    caption = "First 6 posterior draws (ALD Method)",
    digits = 4
   )
}
```

Table 2: First 6 posterior draws (ALD Method)

(Intercept)	wt	hp	cyl	sigma
19.5491	-3.4376	-1.0179	-1.5954	0.7238
19.4543	-2.5142	-0.7504	-2.4742	0.7828
19.5965	-2.6978	-0.5379	-2.8920	0.6449
19.5514	-2.7159	-0.3566	-2.6491	0.5281
19.4124	-3.1352	-0.5566	-2.1270	0.8342
19.4756	-2.9804	-0.8045	-2.3303	0.7001

For the mo.bqr.svy it is recommended to use the summary() method in order to obtain a cleaner and more structured view of the output. This provides posterior mode estimates, EM convergence information, and scale parameters for each quantile and direction.

Convergence Diagnostics

```
methods <- c("ALD", "Score", "Approximate")</pre>
fits <- list(fit_ald, fit_score, fit_approx)</pre>
summ_multi <- lapply(fits, summary)</pre>
summ_df <- do.call(rbind, lapply(seq_along(summ_multi), function(i) {</pre>
  s <- summ_multi[[i]]
  if (!is.null(s$posterior_summary)) {
    df <- as.data.frame(s$posterior_summary)</pre>
  } else if (!is.null(s$per_tau)) {
    df <- as.data.frame(s$per_tau[[1]]$coef_summary)</pre>
  } else {
    stop("Unexpected summary object structure")
  df$Method <- methods[i]</pre>
  df
}))
summ_df <- summ_df[, c("Method", setdiff(names(summ_df), "Method"))]</pre>
knitr::kable(
  summ df,
  caption = "Posterior summary for all methods (Quantile = 0.5)",
  digits = 3
)
```

Visualization functions

The bayesQRsurvey package provides comprehensive visualization capabilities through its plot() method. The plotting system supports both base R graphics (default) and ggplot2 (when use_ggplot = TRUE).

1-. Fitted regression plot Example plotting the fitted regression line using ggplot2, including the credible interval as a shaded band around the fitted line.

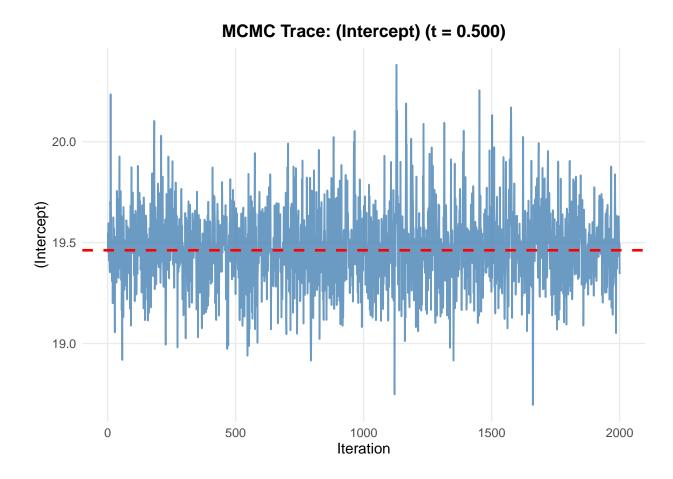

```
plot(fit_ald, use_ggplot = TRUE, show_ci =TRUE)
```

It is possible to hide the points from the plot by setting the argument add_points = FALSE.

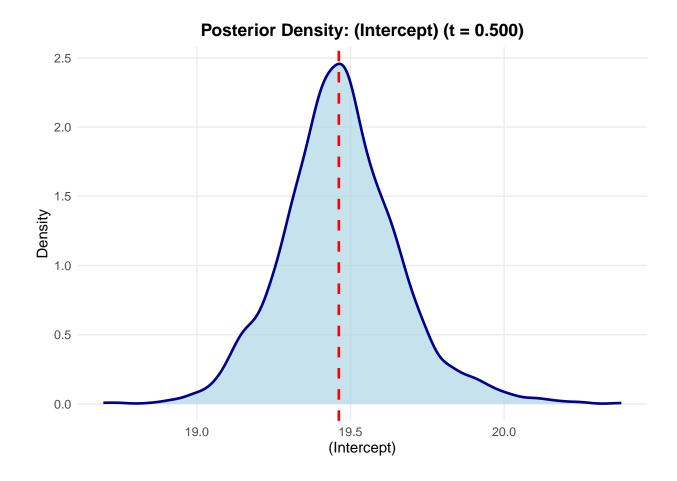

2. Trace Plots Example plotting the MCMC trace of a selected coefficient to assess convergence and mixing across iterations.

```
# Basic quantile plot (requires x_var)
plot(fit_ald, type = "trace", x_var = "hp")
```

3. Density Plots Example plotting the posterior density of a selected coefficient, including the fitted quantile as a reference line.

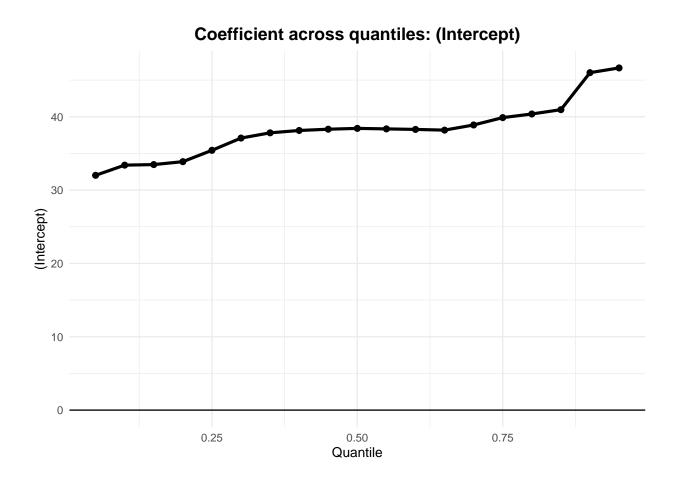

```
# Combined view
plot(fit_ald, type = "density", x_var = "wt")
```

4. Quantile Plots Example plotting the estimated coefficient of a predictor across multiple quantiles.

```
fit_multi <- bqr.svy(
  mpg ~ wt + hp + cyl,
  data = mtcars,
  quantile = seq(0.05, 0.95, 0.05),
  method = "ald",
  niter = 10000,
  burnin = 5000,
  thin = 5,
  verbose = FALSE
)

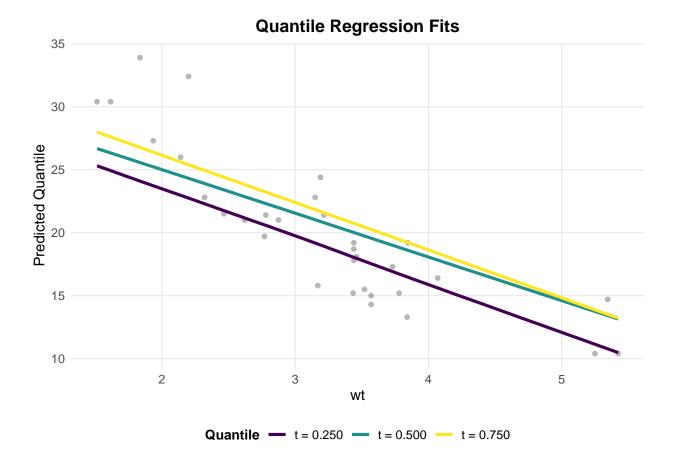

plot(fit_multi, type = "quantile", which = "(Intercept)")</pre>
```

5. Multi-Panel Layouts When working with multiple quantiles, it is often insightful to visualize how the fitted regression lines vary across different levels of the conditional distribution of the response.

The plot() method in **bayesQRsurvey** makes this straightforward: by passing several quantiles in the tau argument, the function can overlay multiple fitted curves in the same plot.

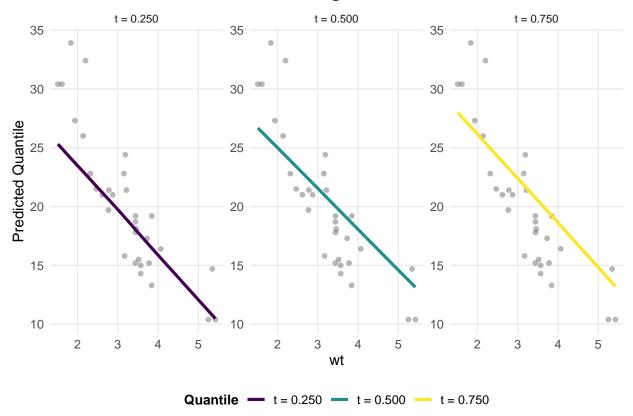

```
# Multi-panel coefficient plot
plot(fit_multi, type = "fit", use_ggplot = TRUE, ncol = 3, combine = TRUE)
```

Alternatively, the user may choose to display separate panels for each quantile by setting combine = FALSE.

```
# Multi-panel coefficient plot
plot(fit_multi, type = "fit", use_ggplot = TRUE, ncol = 3, combine = FALSE)
```

Quantile Regression Fits

Comparison with bayesQR for the MCMC algorithms and EM algorithm

Simulation Study

We conduct a simulation study to illustrate **bayesQRsurvey** capabilities and compare with **bayesQR** using three different sampling designs: Poisson sampling, stratified sampling, and systematic sampling. Each design simulates complex survey data with known population parameters.

The used simulation functions can be found in the data-raw folder simulation.R file

Simulation Execution We run the simulation function and obtain the following values

```
# Simulation parameters
set.seed(42)
N <- 10000  # Population size
n <- 500  # Sample size
n_est <- 5  # Number of strata for stratified sampling
quantiles <- c(0.25, 0.5, 0.75)
# True population parameters
true_beta <- c(2, 1.5)  # Intercept and slope
# Create simulation parameters table
sim_params <- data.frame(</pre>
```

```
Parameter = c("Population size", "Sample size", "Number of strata", "Quantiles", "True Beta0", "True Value = c(N, n, n_est, paste(quantiles, collapse = ", "), true_beta[1], true_beta[2])
)
knitr::kable(sim_params, caption = "Simulation Study Parameters")
```

Table 4: Simulation Study Parameters

Parameter	Value
Population size	10000
Sample size	500
Number of strata	5
Quantiles	0.25, 0.5, 0.75
True Beta0	2
True Beta1	1.5

```
# Generate data for each sampling design

Prostate Dataset

These data come from a study that examined the correlation between the level of prostate specific antigen and a number of clinical measures in men who were about to receive a radical prostatectomy. It is a data

frame with 97 rows and 9 columns and is loaded form the bayesQR package.

```
library(bayesQRsurvey)
library(bayesQR)
# Load Prostate dataset
data(Prostate, package = "bayesQR")
# Center covariates (subtract mean, don't scale)
covars <- Prostate[, colnames(Prostate) != "lpsa"]</pre>
